Technical Guide

DER2
Digital Regulator

Guida Tecnica
Regolatore Digitale DER2

The world's largest independent producer of synchronous alternators 1 – 5,000kVA
INTRODUCTION
This manual contains information on the operation and use of the DER2 digital regulator.

In order to avoid damage to persons and/or property, only qualified personnel, having full knowledge and understanding of the information contained in this manual, should perform the procedures described herein; when power to the unit is on, the voltage present may be lethal for the operator.
All connections must be made with the power off.
The plastic protections on connectors J1 and J2 must not be removed for any reason whatsoever.

MAIN CHARACTERISTICS

1. Architecture of the system
The DER2 is a voltage regulator for synchronous alternators, designed for stand alone working and calibration; to maximize performances, the regulator should be intended as part of a system made up of at least two components: the DER2 (control unit) and a supervision unit, as illustrated in figure 7.
The connectors for connection to and from the power generator and to the supervision unit are located on the DER2 regulator.
The supervision unit can be made up of a personal computer, another "synoptic" device or both; it does not have the function of controlling the system in real time, but allows programming and visualisation of all operational parameters of the DER2 through the embedded USB port.

1.1 Regulator
Since the regulator is designed to control many different types of generators, it must be appropriately configured to obtain the best performance; most of the settings are stored in a non-volatile integrated memory (EEPROM). The first time the regulator is turned on, a default configuration will be present, which satisfies the most widely requested characteristics and is suitable to facilitate installation: the trimmers are active and the inputs for the external potentiometer and the 60 Hz jumper are enabled, therefore the basic calibrations can be performed without the use of additional equipment.
Two versions of the DER 2 and DER 2/A regulators are available; the first one is optimised for Mecc Alte Series 3 to 38 alternators, while the second is optimised for Mecc Alte series 40, 43 and 46 alternators; the two versions differ primarily in the default parameters.
NOTE: the parameter that defines the output voltage (with the VOLT trimmer disabled) is set on 0 (so that the adjustment takes place on the minimum voltage).

1.2 Communications module
The DER2 (which is provided for connection to the COM connector of the DER2) is equipped with an isolated embedded USB port, through which it is possible to set the parameters (for both configuration and operation) and “monitor” operation of the generator.
2. Technical Characteristics of the device installed on board

- Digital controlled regulator, based on DSP
- Suitable for all Mecc Alte self-regulated alternators
- Power connections through 20 poles(1) Fast-On connector (see fig.2)
- Protection of power winding with 5A fast acting fuse
- Signal connections (Pext, 60Hz Jumper, APO) through 10 poles mini Fast-On separate connector
- Environmental temperature: -25°C to +70°C
- Voltage supply: 40Vac÷270Vac (2)(from auxiliary winding, output voltage or PMG)
- Maximum continuous output current: 5Adc
- Frequency range: 12Hz÷72Hz
- Three phase or single phase sensing in all connections (Y-Δ-YY-ΔΔ)
- Single phase or three phase sensing automatic recognition
- Average value of voltage regulation
- Voltage regulation range (sensing) from 75Vac to 300Vac
- Precision of voltage regulation: ± 1% from no-load to nominal load in static condition, with any power factor and for frequency variations ranging from -5% to +20% of the nominal value.
- Precision of voltage regulation: ± 0,5% in stabilized conditions (load, temperature).
- Transient voltage drop and overvoltage within ± 15%
- Voltage recovery time within ± 3% of the value set, in less than 300 msec.
- Programmable Soft start
- Parameters: VOLT, STAB, AMP and Hz settable by trimmers (default), 50/60Hz settable by a “jumper” (default), all parameters programmable via software
- 0÷2,5Vdc or -10÷+10Vdc external voltage for analogical remote control of output voltage
- Remote control of output voltage through external potentiometer (from 25Kohm to 100Kohm)
- Underspeed protection with adjustable threshold and slope
- Overvoltage and undervoltage alarms
- Excitation overcurrent protection with delayed intervention
- Underexcitation alarm/loss of excitation
- Management of temporary short circuits (start up of asynchronous motors)
- High Dynamic Response: load removal management unit
- Open collector output (not insulated) signalling some allarm intervention with programmable activation in respect of each alarm and possibility of the intervention delay and selectable active level
- Allarm conditions storage (type of alarm, number of events, duration of the last event, total time)
- Memorization of the regulator operation time
- USB communications through the embedded USB port.

WARNING: Operation of the DER2 is not specified below 12 Hz.

NOTE (1) The terminals are connected to each other on the board: 2 with 3, 4 with 5, 6 with 7, 9 with 10, 11 and 12.
NOTE (2): with EMI external filter SDR 128/K, see Fig.4 (3m without EMI filter)

#### 4. Block diagram

![Block Diagram](image)

#### 5. High Dynamic Response

The High Dynamic Response module, by a inversion of the excitation voltage, allows a faster reduction of excitation current than conventional regulators and consequently a smaller transient overvoltage as a result of load removal.

The trends of the output voltage and the excitation voltage in function of time of the DER2 controller and a conventional regulator, which does not allow the excitation voltage inversion, are compared in Fig. 2

**WARNING:** The benefits achievable by the High Dynamic Response also depend on an accurate setting of the dynamic response of the regulator: if the response is too slow the control system may not require the excitation voltage inversion, in this case the module would not act and the trend would be similar to a conventional regulator’s one.
INSTALLATION
Upon receipt of the digital regulator, perform a visual inspection to ensure that no damage has been sustained during transportation and movement of the equipment. In the event of damage, advise the shipper, the insurance company, the seller or Mecc Alte immediately. If the regulator is not installed immediately, store it in its original packaging in a dust and humidity-free environment.

The regulator is normally installed in the generator terminal box. It is fixed with two M4x25 screws and must be installed in a location where the temperature does not exceed the environmental conditions foreseen. The regulator is equipped with a 5A fast-acting protection fuse. If necessary, the fuse must be replaced only with a fuse of the same type and rating.

1. Overall dimensions drawings

![Dimensions Diagram](image)

Fig 3

2. Connections

The digital regulator connections depend on the application and excitation system. Figure 1 shows the functional aspect of the connection points to the regulator.

An error in connection may have deadly consequences for the unit. Carefully check to make sure that all connections are precise and in accordance with the attached drawings, before turning on the power.
3. Terminals
Figures 1 and 2 show the connection terminals; the connections must be made using cables having a minimum diameter:
- 1.5 mm² for power cables on terminals from 1 to 22
- 0.5 mm² for signal cables on terminals from 23 to 32

4. DER2 connections
The DER2 regulator has 3 differential inputs, with 2 selectable scales for each of them (see fig. 1):
- scale "H" for voltages between 75V and 150V
- scale "F" for voltages between 150V and 300V

4.1 Connections based on main alternator voltage
Based on the machine connections, and the desired voltage\(^{(1)}\) you can use the three phase or single phase sensing used in one range or the other. Table 4 summarises the connections for the most common voltages.

\(^{(1)}\) Compatibly with the rated characteristics of the alternator
\(^{(2)}\) Sensing only on full phase
4.2 DER2 connections for typical applications
Drawings SCC0301/00, SCC0302/00, SCC0303/00, SCC0304/00 show DER2 regulator connections for typical applications.

In case of sensing 75V-150V, with half-phase reference the typical drawing for three-phase connection is SCC0301/00, while for single phase it is SCC0303/00.

In case of sensing 150V-300V, with half-phase reference the typical drawing for three-phase connection is SCC0302/00, while for single phase it is SCC0304/00.

5. Setting up the regulator
Selection of the sensing scale takes place directly according to the connection on the power terminal board; additional settings can be made with 4 trimmers (VOLT, STAB, AMP and Hz) and 3 jumpers (50/60Hz, JP1 and JP2); the output voltage can also be set with an external analogical signal; additional settings, including the previous ones but excluding jumpers JP1 and JP2, can be made by modifying the 25 parameters stored in a non volatile integrated memory.

5.1 Alternator voltage signals
Terminals 4-22 of connector CN1 are used for voltage sensing.

5.2 Calibrating sensing
A supplementary calibration may be necessary to compensate any existing tolerances on analogical voltage acquisition channels; in this case follow the procedure illustrated below.

1. Write 16384 at location 19 (from the Settings/Advanced Menu)
2. Disable VOLT trimmer (from the Settings/Potentiometers Menu)
3. Disable Vext (from the Settings/Advanced Menu)
4. The parameter present in parameter P[5](if three phase sensing) or p[6] (if single phase sensing) has to be calibrated. Calibration should be adjust in order to obtain 225V from the generator output when the sensing is cabled to U_FB (9-10-11-12) and U_FG (6-7), or to 125.5V if connected U_FB (9-10-11-12) and U_HG (6-7). Please note that a parameter increment will result in a voltage reduction of the system. It is recommended to measure the voltage output with an instrument capable to catch the average value of the voltage.

5. In order to ensure that the value of voltage (available also at location 36) is the same as the value measured at point 6, calibrate the data at location 7, reading the value of Volt box in the “status” area of Settings/Advanced menu.

6. Enable the trimmers again, if it is desired to have them active (from the Settings/Potentiometers menu).

7. Enable Vext (from the Settings/Advanced Menu) if you want to be active.

6. 50/60 Signal
A jumper is located on the 50/60 input (terminals 25 and 26); if enabled from the Configuration Menu, it provokes the commutation of the underspeed protection threshold from 50·(100%-αHz%) to 60·(100%-αHz%), where αHz% represents the position relative to the Hz trimmer or the percentage value entered at parameter [21 (where 10% corresponds to 16384).

7. APO Contact
The acronym APO stands for Active Protection Output: (connector CN1 terminals 23 and 24) 30V-100mA non-insulated open collector transistor, normally closed, if the "APO Invert" flag (2) is active (default), opens (with a delay that can be programmed from 1 to 15 seconds) when, of all the alarms, one or several separately selectable alarms are active.

NOTE (1): Software DxR Terminal
SCC0301/01: Three phase sensing 75V-150V
SCC0303/01: Single phase sensing 75V-150V
SCC0304/01: Single phase sensing 150V-300V
SCC0305/01: Single phase sensing 300V-600V
SCC0306/01: Single phase sensing 300V-600V
(generator in three-phase ZIG-ZAG connection)
8. Remote control of voltage

The Pext input (terminal 30) and ±10V (terminal 32) allow to obtain remote control of the output voltage by means of a DC signal or an external potentiometer. The output voltage can be controlled by software as well with the P[19]. The excursion range and gain of the remote control can be set independently by software despite the output voltage control device system used (potentiometer, VDC signal or P[19]). If DC voltage is used, it will take effect if it is within the range 0Vdc/2.5Vdc or -10Vdc/+10Vdc, when connected between terminals 30 and 29 and subjected by jumpers JP1 and JP2; for values exceeding the aforementioned limits (or in the event of disconnection), two options are possible: not to take the set point of external input and return to regulation to the voltage value set with the trimmer (if enabled) or with parameter P[19], or keep the minimum (or maximum) value of voltage that can be reached (see figures 3a and 3b). The two options can be set with the RAM Voltage CTRL flag in the Settings/Advanced menu corresponding to the bit B7 of the configuration word P[10] (see PARAMETERS AND OPERATIONAL DATA - Para. 2). The setting relative to the Vext input are summarised in table 5.

NOTE: the source of DC voltage must be capable of absorbing at least 2 mA.
In making adjustments it is recommended not to exceed the nominal value of voltage of the alternator beyond ±10%

### Relationship between analogical input and output voltage

![Figure 3a: without saturation of the output voltage upon reaching the input voltage limits.](image1)

![Figure 3b: with saturation of the output voltage upon reaching the input voltage limits.](image2)

<table>

</tr>
</tbody>
</table>

With a 100Kohm linear potentiometer connected as shown in figure 4a, you have the full excursion set with parameter P[16] (with the default value P[16]=4608 there is an excursion of ± 14%); with a 25Kohm linear potentiometer in series with a 3.9Kohm resistor, connected as shown in figure 4b, the effect of the external potentiometer is cut in half (with the default value P[16]=4608 there is an excursion of approximately ±7%).
9. VOLT, STAB, Hz and AMP Trimmers
The trimmers are enabled by the software DxR_Terminal; if they are not enabled, they do not perform any function.
The VOLT trimmer allows adjustment from about 75V to about 150V or from about 150V to about 300V.
The STAB trimmer adjusts the dynamic response (statism) of the alternator under transient conditions.
The Hz trimmer allows for a variation of the "low speed protection" of up to –20% with respect to the nominal speed value set by the 50/60 jumper (if activated) or by the 50/50 box in the Settings/UFLO&LAM menu (at 50 Hz the threshold can be calibrated from 40 Hz to 50 Hz, at 60 Hz the threshold can be calibrated from 48 Hz to 60 Hz).
The AMP trimmer adjusts the excitation overcurrent protection intervention threshold.

10. USB Communications
The COM connector is RESERVED for connection to supervision unit through the dedicated USB cable (see fig. 7).
For the communication, the regulator implements a subsystem of the ModBus standard; the DER2 performs a “slave” operation the address of which is stored in the DER2 EEPROM and is set during configuration.
The “Master Unit” is made up of a PC or other dedicated equipment and can access the parameters and functions of the regulator.

The master unit has the following possible functions:
- Repetition, or visualisation, of the generator status variables, even from a remote location
- Setting of single parameters
- Uploading and downloading of settings files
- Status readings (alarms, measuring variables)
- Readings of the alarm memory information
PARAMETERS AND OPERATING DATA

1. ModBus registry list

An EEPROM memory is used to store configuration parameters and other information that must not be lost when the generator goes off. Parameters can be read/written and machine operational settings entered through USB connections (with module USB2DxR). Two versions of the regulator are available, called DER2 and DER2/A; they differ primarily in the default value of several parameters. Table 6 shows a complete list of the parameters that can be set, which define all the operational conditions of the regulator.

Note: Locations are ordered to separate the parameters of individual regulators (S.N.; SW versions and calibration) from settings foreseen, in order to facilitate programming of regulators with the same settings but different S.N., SW versions and calibrations. The parameters from 0 to 9 are adjusted at the factory for each regulator. The parameters from 10 to 30 can therefore be freely copied from one to another.
2. Configuration word (Parameter P[10])

Configuration of the regulator takes place by setting the individual bits of parameter P[10]. Each of them enables or disables at least one function, on the basis of the fact that its value is respectively 1 or 0. If the "DxR Terminal" programme is used (see technical guide "Interface communication USB2DxR"), the setting is simplified by the use of the dedicated flags in the different menu corresponding to the specific bit which enables/disables each function.

Alternatively, the DER2 can be configured by directly setting the value of the P[10] parameter; in this case the value is calculated before entry, summing the numbers indicated in the column "Value" of Table 7, corresponding to the functions it is desired to enable.

For example, the default configuration calls for the bits B2, B4, B5 and those from B8 to B12 to be enabled. The corresponding value is therefore: P[10]=4+16+32+256+512+1024+2048+4096=7988.

NOTE (1): only with single-phase reference
NOTE (2): if analogical input is disabled
NOTE (3): for analogical input

3. RAM location reference, activation of saturation in analogical remote control

The RAM Voltage CTRL Flag (corresponding to bit 7 of the P[10] configuration word) performs two functions:

1. If the Pext hardware input is enabled (Flat Ext. Input corresponding to bit 12 of the P[10] configuration word), as previously described, the RAM Voltage CTRL Flag activates saturation of output voltage when the analogical control voltage reaches the limit foreseen for input, to which it is applied (see Para. 8 Remote control of voltage).

If saturation is enabled, in the event of removal of the Vext/Pext connection (due to accidental opening, for example) the voltage goes to the maximum value set in parameter P[16] (+14% by default).

2. When Pext is disabled by hardware, the indicated flag defines the value to be used by the software control of the output voltage. If RAM Voltage CTRL is deactivated (B7=0), the non volatile parameter P[15] is used (therefore following shut down and restart of the regulator, the last value memorised remains set); on the start up the location L[49] is initialised with the value of parameter P[15] and is kept aligned to that value. Editing of location L[49] has no effect in this working condition. If RAM Voltage CTRL is active (B7=1) the volatile location L[49] is used for software remote control of the output voltage (when the regulator is energized, the value is stored. If the regulator is shut down, the value is lost). This function is particularly useful for the applications of alternators in parallel with grid, when the regulation of the reactive power exchanged is controlled by means of a third party supplied digital supervisor.

5. Fourth Status Word (Location L[39])

Location L[39] indicates (almost in real time) the active configuration at any given time; it is not a simple replication of the value recorded in parameter P[10], however, inasmuch as the bits B2, B6 and B14 adjust their value only on the basis of the configuration set, but also of the effective operational status of the DER2 at that time; for example, if the regulator is connected with three phase sensing, even if bit B6 of the configuration word is set on 0 (automatic recognition of single phase – three phase activation), bit B6 of location L[39] will have a value of 1; similarly, if the 60 Hz jumper is engaged and reading is enabled 8Bit B4 of parameter P[10] set on 1), bit B14 of location L[39] will have a value of 1 even if the corresponding bit B14 of the configuration word is set on 0.

The values of the fourth word of status (location L[39]) are shown in table 10, on the basis of the type of the regulation and nominal frequency.

NOTE (1): depending on the sensing and nominal frequency
NOTE (2): software configuration, with jumper 50/60 disabled
1. Voltage

1.1 Setting voltage.

Setting can take place through the trimmer or software: on sensing inputs 6/7 – 10/11/12 (with bridge 8-9), 15-16 and 20-21, the voltage can be set between 75+150 Vac (scale H); on sensing inputs 4/5 - 9/10/11/12, 14-17 and 19-22 between 150+300 Vac (scale F).

There are two ways to set from minimum to maximum value:

1. With the VOLT trimmer, which must be enabled by the Settings/potentiometers menu of DxR Terminal software
2. With parameter P[19] (The Volt trimmer must be enabled from the Settings/Potentiometers menu: the value 0 corresponds to minimum voltage, 16384 corresponds to the intermediate value (respectively 112.5 V and 225 V), while 32767 corresponds to maximum voltage.

The setting is facilitated using the software DxR Terminal, through Settings/Potentiometers menu.

It is possible to vary voltage with respect to the value set, with the Pext input (terminals 29-30) if enabled from the area Pext/Vext in the Settings/Advanced menu, with a 25Kohm or 100Kohm potentiometer, with a range of variation that can be programmed up to ±100% (parameter P[16]. The default setting is ± 14%, even if it is opportune not to exceed ±10%). Alternatively, variation can be made with continuous voltage applied on Pext (terminal 30) or ±10V (terminal 32), based on the value of that voltage. If the Pext voltage is disabled, it is possible to vary the voltage with parameter P[15] or location L[49]. For additional details see the paragraph "Remote control of voltage".

1.2 Soft Start

In the event of fast start up of the prime mover or sudden regulator excitation with the generator running at nominal speed an uncontrolled regulator could result in a temporary generator overvoltage or in a transitory prime mover overload due to the high peak of excitation current.

These effects can be minimised by setting parameter “Delay” and “Excitation Limit” in the area “Soft-Start” of the Settings/Advanced menu, corresponding to parameters P[8] and P[9] : during starting, they determine a limit of the excitation current.

Parameter P[8] sets the duration of the excitation current limitation, namely the value of the parameter corresponds to the number of periods in which the limitation is active. The default value is P[8]=0 which corresponds to deactivation of the soft start. Considering that in most cases the alternator is already at nominal speed, an estimate in temporal terms (corresponding to the setting “Delay” in Soft-Start area) for 4 pole machines, may be obtained with the formula:

\[ t_{\text{lim}} = P[8] \cdot \frac{1}{f_n} = P[8] \cdot \frac{30}{\omega_n} \]

Where \( f_n \) = nominal frequency in Hz or \( \omega_n \) = nominal speed in R.P.M

The parameter P[9] sets the excitation current limit: the value P[9]=0 is setting to zero the excitation current, while the maximum value P[9]=32767 is removing the current limitation. The default value is P[9]=32767. When the interval of action of the soft start has been exceeded, the output voltage moves to the value set. The rapidity of the change is set by parameter P[18] (see paragraph on “Slow voltage variations”)

---

**The optimal values of “Delay” and “Excitation limit” (parameters P[8] and P[9]) depend a great deal on the type of alternator and final application and it must be found through experimentation. An inappropriate setting of parameters P[8] and P[9] could cause failure of the alternator to excite itself.**

By way of example, for high power alternators of the ECO46 series, the following settings may be experimented: Delay=1280ms (P[8]=64) and Excitation limit=50% (P[9]=16384); for low power alternators of the ECP3 series, the effects of a reduction of both the duration and limitation of the current may be experimented, such as Delay=320ms (P[8]=16) and Excitation limit=3.72% (P[9]=4096).
1.3 Slow voltage variations
In the event of rapid variation of the reference, a procedure of "slow" variation has been foreseen: in response to a step variation, parameter P[18] determines the rapidity with which the transition is made. A value of 1 involves the slowest possible variation; a value exceeding 100 involves an almost immediate variation. The value 0 disables any variation.

2. Stability
2.1 Adjustment of stability
The regulator diagram is shown in figure 8.

The values of the proportional and integral gain (K_P and K_I respectively) depend on the position of the STAB trimmer if enabled, or the value of parameter P[20] if the trimmer is disabled. The value of the proportional gain K_P also depends on the value of the P[11] parameter. The value of the integral gain K_I depends on the values of parameters P[12] and P[13] and, only for the standard DER2 with the STAB trimmer enabled, even on the 50/60Hz setting. In the other DER2 versions, for example DER2/A (black box), the integral gain K_I does not differ no matter how the 50/60Hz setting is set. The numeric elaborations carried out by the DER2 for obtaining the proportional and integral gain values are given in the block diagrams in figures 9a, 9b and 9c.

fig. 9a: drawing of the numeric elaboration of the proportional and integral gain by a DER2 (standard) with the STAB trimmer enabled
If the STAB trimmer is enabled (STAB Flag Trimmer present) its angular position, available at location L[33], is transformed by the \( F_{c_{STAB}} \) function into the numeric value available at location L[53] (figs. 9a and 9b). If the STAB trimmer is disabled, the value of location L[53] directly becomes the value set using the \( P[12] \) parameter (fig. 9c).

The proportional gain \( K_P \) is obtained by multiplying the value of location L[53] by a coefficient that depends on the value given in parameter \( P[11] \).

\[
\begin{align*}
\text{Trimmer STAB} & \quad L[33] \\
& \quad F_{c_{STAB}}() \\
& \quad L[53] \\
& \quad P[13] \\
& \quad L[54] \\
& \quad 2^{P[12]} \\
& \quad 2^{P[11]} \\
& \quad K_I \\
& \quad K_P
\end{align*}
\]

fig. 9b: drawing of the numeric elaboration of the proportional and integral gain by a DER2/A with the STAB trimmer enabled

The integral gain, available at location L[54] minus the multiplication by a coefficient, depends on the value of the proportional gain at location L[53]: in the standard DER2 (standard) with the STAB trimmer enabled (STAB Flag Trimmer present) the value of location L[53] at 50Hz is transformed by the function \( F_{c_{ig_{50}}} \) and by the multiplication of the value of parameter \( P[13] \), in the numeric value available at location L[54]; at 60Hz the transformation function is \( F_{c_{ig_{60}}} \), different from that at 50Hz, (fig. 9a); in the other versions of the DER2 (fig. 9b), for example DER2/A (black box), or if the STAB trimmer is disabled (fig. 9c), not only is there a difference between the integral value at 50Hz and at 60Hz, but even the value of location L[54] is obtained by simply multiplying the proportional gain at location L[53] by the value of parameter \( P[13] \).

\[
\begin{align*}
& \quad L[53] \\
& \quad P[13] \\
& \quad L[54] \\
& \quad 2^{P[12]} \\
& \quad 2^{P[11]} \\
& \quad K_I \\
& \quad K_P
\end{align*}
\]

fig. 9c: drawing of the numeric elaborations of proportional and integral gain by all DER2 with STAB trimmer disabled

In both cases, the effective integral gain \( K_I \) is obtained by multiplying the value of location L[54] by a coefficient that depends on the value given in parameter \( P[12] \).

The mentioned coefficients can take on values of 1, 2, 4, 8, 16, 32 or 64 according to the values written in parameters \( P[11] \) (for proportional gain) and \( P[12] \) (for integral gain); these values represent the value assigned to base 2 (fixed) to obtain the required coefficient (e.g. parameter \( P[11] = 4 \Rightarrow \) multiplication coefficient of the proportional gain = \( 2^4 = 16 \), \( P[12] = 3 \Rightarrow \) multiplication coefficient of the integral gain = \( 2^3 = 8 \)).

The following tables show, for every three-phase machine on 50Hz and 60Hz, the STAB trimmer calibration which allows increased speed of response to the transistor with the generator in stand-alone operation. In case of different applications (for example alternators reconnected in single-phase, in parallel among them or in parallel with the grid, with motors having less than 4 cylinders and so on) it may be necessary to realign the STAB trimmer calibration.

If the voltage cannot be stably adjusted for permanent operation and/or in the transient by the STAB trimmer settings, it may be necessary to vary one or more stability adjustment parameters: \( P[11] \), \( P[12] \) and \( P[13] \) the description of which is given in table 6.

**WARNING:** The benefits achievable by the High Dynamic Response also depend on an accurate setting of the dynamic response of the regulator: if the response is too slow the control system may not require the excitation voltage inversion, in this case the module would not act and the trend would be similar to a conventional regulator’s one.

DER2 digital regulator instruction manual - rev. 01 - pag. 25
3. EXCITATION OVERCURRENT

3.1 Description
The DER2 regulator is equipped with an excitation (main rotor) winding temperature estimator. An estimate of the temperature (in relative values) is available in real time (and it can be read) in location 45; in the lower part of the main window of the DxR terminal software there is a graphic representation of location 45. The progress of the temperature is of the exponential type (see figure 9). Through parameter P[22] or the AMP trimmer, it is possible to define a limit (which involves intervention of alarm 5) to the excitation voltage and therefore to the temperature.

The function of this alarm is not only to signal an excessive temperature, but it also has an active function in reducing the cause. In fact, an adjustment ring takes control of the voltage generated when the threshold is exceeded: This reduces the voltage to the point of reducing the excitation current by a value compatible with the ability of thermal dissipation of the machine. The stability of the regulation in case of overexcitation alarm, if necessary, may be adapted to the application by varying the value of parameter 28. For an increased protection of the electrical machine, the excitation overcurrent protection was extended to the whole speed interval (frequency) of the alternator, particularly for the lower frequencies, to a preset threshold (56.7Hz with the jumper inserted between the 25 and 26 terminals of connector CN1, if enabled, or, otherwise, if the 50/60, 49Hz setting is enabled) the protection intervenes with an effective threshold (relative to the one set through the AMP trimmer or parameter 22) reduced proportionally to the frequency.

The extent of this reduction depends on parameter 29 which is by default set to an adequate value for the standard alternators, used in three-phase in nominal voltage.

An increment of the value of P[29] determines a bigger reduction of the intervention threshold, based on the frequency reduction, a decrease of the value of P[29] determines a smaller reduction of the intervention threshold.

As you can see in figure 9, when the estimated temperature (represented by the continuous line) reaches the threshold value, the reduction of excitation current (and consequent drop in voltage generated) brings about the stabilisation of the temperature near a limit value.

**WARNING:** If the magnetic gain of the alternator is high, unstable events may occur when the protections intervenes, therefore it is necessary to adjust parameter 28 (usually by reducing its value).

When the alternator works with reduced load and speed, overheating, which is dangerous to the integrity of the machine, might occur, if the overcurrent protection threshold is not sufficiently reduced when reducing the frequency.

---

![Figure 9](image.png)
3.2 Calibration with a supervision unit
To calibrate the overload protection, when the machine is cold, perform the following procedure:
1) turn the AMP trimmer fully clockwise (if enabled from the Settings/Potentiometers menu) or write 32676 in location 22
2) feed the alternator an overload having cos phi = 0.8 or cos phi = 0 respectively equal to 125% or 110% of the nominal load
3) read the value displayed at location 45 2 minutes after overload application
4) if the AMP trimmer is enabled turn it anti-clockwise until the value read at location 55 becomes equal to the value read at point 3 (location 45); the operation is simplified a lot by using the DxR terminal software which provides, in the lower part of the main window, a graphic representation of the time evolution of locations 45 (“real excitation”, red line) and 55 (“excitation threshold” - yellow line): the intervention threshold must be calibrated so that the yellow line should intersect the red line when, from the application of the overload, the time specified at point 3 has passed.
5) if the AMP trimmer is not enabled, write the value read at point 3 (location 45) in location 22.
6) Alarm 5 should set off (visible both on the main panel of the DxR Terminal and through a change in the LED flash) and the voltage should start to decrease
7) If the load is removed, alarm 5 disappears after a few seconds and the generator voltage goes back to the nominal value.

3.3 Calibration without a supervision unit
NB: this calibration can be performed only if the AMP trimmer was previously enabled.
To calibrate the overload protection, perform the following procedure:
1) turn the AMP trimmer fully clockwise
2) feed the alternator an overload having cos phi = 0.8 or cos phi = 0 respectively equal to 125% or 110% of the nominal load
3) after two minutes slowly turn the AMP trimmer anti-clockwise until you get a reduction of the generator's voltage value and the activation of alarm 5 (visible through a change in the LED flash)
4) Calibrate the AMP trimmer so as to get an output voltage value of 97% of the nominal value: alarm 5 is still active.
5) If the load is removed, alarm 5 disappears after a few seconds and the generator voltage goes back to the nominal value.

NOTES: If the machine is used in single phase or voltages different to the ones set by the producer, a recalibration of the overexcitation protection might be necessary.
If it is not possible to apply the prescribed overload, the overexcitation condition may be simulated by adequately increasing the regulated voltage so as to get an excitation current equivalent to the overload current.

4. Underspeed
4.1 Description
For speeds lower than a programmable threshold, the machine voltage is no longer constant, but is regulated proportionately with the frequency at a ratio, which is also programmable, as shown in figure 10a e 10b. The intervention threshold depends upon:
- the status of jumper 50/60 (terminals 25 and 26) if enabled from the Settings/UFLO&LAMS Menu.
- the status of the 50/60 setting in the Settings/UFLO&LAMS Menu
- the position of the Hz trimmer if enabled from the Settings/Potentiometers Menu
- the value entered at parameter P[21] (ref. Settings/UFLO&LAMS menu or area Transmit/Receive of Settings/Advanced menu).
Activation of the function with voltage proportionate to the frequency is signalled by activation of alarm 6 (visible from the DER2 Terminal control panel and due to a change in the flashing indicator light).

Parameter P[21] (equivalent to the Hz trimmer) sets the Underspeed protection intervention threshold; if this is set on 26214, the protection cuts in at 48 Hz (if the 50/60 jumper and 50/60 flag in the Settings/UFLO&LAM menu are not present) or at 57.5 Hz (if the 50/60 jumper is enabled or the 50/60 flag is active in the Settings/UFLO&LAM Menu). Values between 0 and 26214 proportionately lower the threshold, respectively to 40 Hz and 48 Hz; values between 26214 and 32767 proportionately raise the threshold, respectively to 50 Hz and 60 Hz.
Once the underspeed protection has intervened, the frequency is proportionately reduced, as indicated in figure 11a and 11b.
Parameter P[23] sets the slope of the voltage/frequency curve; the default value is 1875. An increase in the value of P[23] involves a greater reduction of the voltage as a function of the reduction in frequency. A decrease in the value of P[23] involves a lower reduction of the voltage until the limit of P[23]=0, which means that there is no reduction in voltage. The above-mentioned calibrations are simplified a lot by using the DxR terminal software which allows, in the Settings/UFLO&LAMS menu, through a graphic interface, to change parameters 21 and 23 (with a concurrent disabling of the Hz trimmer) providing the preview of the V/f ratio in the setting phase.

**WARNING:** Overheating could occur, which is dangerous for the machine, if the voltage is not lowered enough to decrease the excitation when the alternator is functioning at a reduced speed.

### 4.2 Calibration with a supervision unit

Use the following procedure in order to calibrate the underspeed protection:

1. If the machine has to operate at 60 Hz, make sure the bridge, between terminals 25 and 26 is inserted, or activate 50/60 (ref. Settings/UFLO&LAMS menu).
2. If the Hz trimmer is enabled, the value of the protection intervention threshold is read at location L[34], otherwise it is entered directly at parameter P[21].
   - The value 26214 entered at parameter P[21] (or read at location L[34]) corresponds to an intervention at 48/57,5 Hz (depending on whether 50/60 is activated or not).
   - Values between 0 and 26214 correspond to an intervention that varies from 40/48 Hz to 48/57,5Hz.
   - Values between 26214 and 32767 correspond to an intervention that varies from 48/57,5 Hz to 50/60Hz.

   The operation is much facilitated by the use of the DxR terminal software which provides a graphic representation of the time evolution of the measured frequency (red line) and of the intervention threshold (green line)

3. When the speed decreases under the threshold value the voltage of the generator starts to diminish and alarm 6 is simultaneously visualized on the LED and on the main window of the DxR Terminal software
4. By increasing speed, the generator voltage will normalise and the 6 alarm will disappear.

### 4.3 Calibration without a supervision unit

NOTE: This calibration can be performed only if the Hz trimmer and 50/60 jumper have been previously enabled.

Use the following procedure in order to calibrate the under speed protection:

1. Rotate the Hz trimmer entirely in the counter clockwise direction.
2. If the machine has to operate at 60 Hz, ensure that the bridge is inserted between terminals 25 and 26.
3. Bring the generator to 96% of the nominal speed.
4. Slowly turn the “Hz” trimmer, rotating it clockwise until the generator voltage begins to drop and ascertain that the indicator light simultaneously begins flashing rapidly.
5. By increasing speed, the generator voltage will normalise and the alarm will disappear.
6. Set the speed to the nominal value.

![fig. 11a: Underspeed and Overspeed protection, P[21] and P[26]](image1)

![fig. 11b: Voltage slope in underspeed protection, P[23]](image2)
5. Overspeed
Parameter P[26] sets the overspeed alarm intervention threshold; if it is set on 0, the signal cuts in at 55 Hz (if the 50/60 jumper and 50/60 setting in the Settings/UFLO&LAMS Menu are absent) or at 66Hz (if the 50/60 jumper is present and enabled or the 50/60 flag in the Settings/UFLO&LAMS Menu is activated). Values between 65535 (-1) and 32768 (-32767) lower the threshold proportionately to 50 Hz and 60 Hz, respectively; values between 0 and 32767 raise the threshold proportionately, respectively to 60 Hz and 72 Hz; refer to the broken lines in figure 10a.

6. Other parameters
6.1 Vout / Vaux Ratio
In order to guarantee sufficient feeding voltage at speeds lower than the Hz protection intervention threshold, a limit to the reduction of voltage has been foreseen, as a function of frequency. The limit concerns regulated voltage (Vout). Should the DER2 be powered through an auxiliary winding, it must be born in mind that the voltage generated by the winding (Vaux) may not have the same Vout value; Vaux is considered proportionate to Vout and the proportional coefficient is determined by parameter P[14].
If the DER2 is powered directly by the regulated phase, parameter 14 should be set on 0; in case it is powered by auxiliary winding or PMG, the voltage (Vaux) must be measured, in no-load conditions and with output voltage regulated on the nominal value (Vout); the value of parameter P[14] can be obtained with the following formula:

\[
P[14] = 32767 \cdot \left( \frac{Vout}{Vaux} - 1 \right)
\]

6.2 V/F slope at start up
Parameter P[24] sets the slope proper voltage / frequency at start up. After the underspeed alarm frequency threshold has been exceeded (set by parameter P[21] or by the Hz trimmer), the work ramp is used (parameter P[23]). The default value is 1250; an increase in the value of P[24] will cause a greater reduction of low frequency voltage; a decrease in the value of P[24] will cause a lower reduction in voltage, up to the limit of P[24]=0, which means that no reduction in voltage will take place.

![WARNING: If the voltage is not lowered enough with low frequency and the alternator is operating in these points, overheating could develop that is dangerous for the machine.]

6.3 Short circuit time
Parameter P[25] defines the operating time with the alternator short circuited, which is expressed in tenths of a second (from 0.1 seconds to 25.5 seconds); after this period of time the regulator goes to the blocked status; a value of 0 disables the blockage.

6.4 Intervention threshold of low excitation alarm
If the measured value of excitation voltage does not fall within a preset value range, the low excitation or the excitation lost condition is signaled (visible on the main panel of the Dxr Terminal through the A-08 alarm indicator); no other action is performed by the regulator, except for the switching of APO (if set). The numeric value identifying in real time the excitation condition is available at location L[56]; the upper detection threshold cannot be modified while the lower threshold can be configured through parameter P[27]. The alarm is activated when the value assumed by location L[56] is higher than the upper threshold or lower than the value assumed by parameter P[27]. For the generators in stand-alone operations, the loss of excitation, on a working regulator, implies also the activation of the low voltage alarm. The underexcitation / loss of excitation alarm is mainly intended for the applications in grid-parallel mode, provided that the regulator stays fully operational (for instance with sufficient residual voltage, direct supply from the phase or from PMG).

![WARNING: In case of parallel operation of the generators and, most of all, in case of grid-parallel mode, given that the activation of the underexcitation/loss of excitation alarm does not imply any other action, except for the signalling and switching of APO (if enabled), the protection of the system is transferred to at least an appropriate management of the above-mentioned signalling. However, no guarantee is offered for the capacity of the exclusive use of this protection to safeguard the system from all the possible functional anomalies correlated to underexcitation / loss of excitation.]

DER2 digital regulator instruction manual - rev. 01 - pag. 29
The status of active alarms is stored at location L[38], which can be read with the USB connection. The index of bits that have a value of 1 corresponds to the active alarm. If the regulator is correctly working (no alarm active) the bit 11 will be high.

Example:
Location 38 = 48 = 0000000000110000₂ means that Bits B5 and B4 are at 1, therefore alarms A6 and A5 are active.

1. Alarm signals with the indicator lights

During normal operation and a duty cycle of 50% (OK in fig. 11) an indicator light mounted on the board flashes every 2 seconds; it flashes differently in the event of intervention or alarm, as indicated in fig. 11.

---

**fig.12**
2. Description of alarms

<table>
<thead>
<tr>
<th>N.</th>
<th>Description of event</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>EEPROM checksum</td>
<td>Verified upon start up (after DSP reset and initialisation of the peripheral). The actions undertaken are: signalling, locating of default settings, saving in EPROM and regulator blockage. When the machine is switched on again, if the EEPROM is damaged, the alarm will be repeated. Otherwise the regulator will begin to function with default parameters.</td>
</tr>
<tr>
<td>2</td>
<td>Over Voltage</td>
<td>The alarm does not determine a change in the LED flash, the APO output is active and the alarm is memorised. This can be caused by abnormal operating conditions (such as overspeed or overloading) or by a breakdown of the regulator. The over voltage alarm is activated if the output voltage is lost. The over voltage is calculated using an opportune template, as a function of the speed and is inhibited during transition, for 2 seconds. In the template for the calculation the threshold is set at 5% above the nominal value.</td>
</tr>
<tr>
<td>3</td>
<td>Under voltage (@ $\omega_N$)</td>
<td>The alarm does not determine a change in the LED flash, is stored and the APO output is active. The under voltage is calculated using an opportune template as a function of the speed (which can be seen in the description of the over voltage alarm); in the template for the calculation the threshold is set at under 5% the nominal value. It intervenes only above the underspeed alarm threshold; it is practically inhibited by this. It is also inhibited in the ent of intervention of the Excitation over voltage and during transients.</td>
</tr>
<tr>
<td>4</td>
<td>Short circuit</td>
<td>The alarm is disabled under 20 Hz, is visualised upon activation of the action and memorised. Tolerated short circuit time goes from 0,1 to 25,5 seconds (programmable in 100 ms steps); then the regulator is blocked after saving DD and TT and signals the STOP status. With the time in short circuit set on zero, the blockage is disabled. The STOP condition causes a fall in excitation, with consequent switching off and successive restarting of the regulator and therefore repetition of the cycle.</td>
</tr>
<tr>
<td>5</td>
<td>Excitation Overcurrent</td>
<td>The function of this alarm is not only to signal an excessive temperature, but it also has an active function in reducing the cause. In fact, there is an adjustment ring that takes control of voltage after the threshold has been exceeded; the action involves reduction of the excitation current and therefore output voltage. The available parameter is the &quot;current threshold&quot;, which determines the balanced value at which the system is stabilised. The alarm is signalled and stored. For calibration see the paragraph on excitation overcurrent.</td>
</tr>
<tr>
<td>6</td>
<td>Underspeed</td>
<td>Signalling (immediate) and activation of the V/F ramp. This alarm also appears when the machine is started and stopped. The alarm is not saved among EPROM data. The alarm intervention threshold depends upon the status of the 50/60 jumper (hardware or software) and on the position of the Hz trimmer or the value of parameter P[21]. Under the threshold the V/F ramp is active.</td>
</tr>
<tr>
<td>7</td>
<td>Overspeed</td>
<td>This is visualised in the same manner as the underspeed alarm and does not involve actions on control, but the alarm is stored. The overspeed condition may provoke an over voltage as in the case of capacitive load. The threshold can be set with parameter P[26].</td>
</tr>
<tr>
<td>8</td>
<td>underexcitation /loss of excitation</td>
<td>The alarm does not determine a change in the LED flash, enables APO output and is memorized. The alarm condition is recognized by a underexcitation / loss of excitation observer, available for reading at location L[56]; if the value of L[56] is higher than the upper (fixed) threshold or lower than the value of the lower threshold (parameter P[27]), A-08 is activated. The alarm is inhibited during transients.</td>
</tr>
</tbody>
</table>

NOTE: Though the voltage is continuously regulated, the DER2 will switch off if the frequency goes under 20Hz. To reset the system it is necessary to stop completely the alternator.
3. APO Output
The APO output status ((Transistor open collector Active Protection Output - connector CN1 terminals 23 (common) and 24 (collector)) depends on:
- whether some alarms are activated or not
- setting of parameter P[17]
- setting of the "APO Invert" flag

In normal operating conditions it is closed. It opens (with a configurable delay from 0 to 15 seconds) when, of all the alarms, one or several separately selectable alarms are active and the "APO Invert" flag is active or, immediately, in case of absence of power supply to the regulator; if the "APO Invert" flag is inactive the APO output is inverted (open in normal operating conditions or with regulator switched off, closed, with a configurable delay, in case of one or several active selected alarms).

The selection of which alarms trigger the activation of A.P.O. depends on the value written at location 17. The transistor is closed both when no alarm is active and when, even if the alarm is active, the corresponding enabling bit is set to 0.

The value to set at location 17 is made up of 2 parts: one part allows selection of the alarms which activate the contact, the other one allows setting the intervention delay. To calculate the value to set at location 17 use the following procedure:

a) In relation to table 15. Add up the decimal numbers corresponding to the alarms for which you want APO to be activated obtaining number B. (Example: if you want APO to be activated for overvoltage and overspeed, you get B = 2 +64 = 66)

b) Multiply the delay you want (integer values from 0 to 15 seconds) by the fixed value 4096. You get number A = (0..15) * 4096. (Example: if you want a 5 seconds delay, you get A = 5 * 4096 = 20480)

The sum A + B must be written at location 17 (In the preceding example 20480 + 66 = 20546)

The configuration is simplified a lot by the use of the DxR terminal software which has the APO settings menu dedicated to this purpose.

4. DER2 operation time
If the regulator is working correctly (no alarm) A12 will be active and the bit 11 will be High at location L[38]. When we see one alarm, the A12 is deactivated, bit 11 is reset at location L[38] and operation time is stored.

The total operation time of the regulator is obtained, after the download of the alarms, by adding all the times TT (last column of the file .alr).

For this procedure please refer to the "DownLoad Alarm" function of the Upload/Download Menu of DxR Terminal Software, see Technical guide “Interface communication USB2DxR”.

DER2 digital regulator instruction manual - rev. 01 - pag. 32
APPENDIX : DER2 SET UP ON A TEST BENCH

The operations of functional checkout and parameter setting may turn out to be easier if they are performed on a test bench rather than with the regulator connected to the alternator.

The connection diagrams of the DER2 and the supervision unit are shown in figures 13a, 13b or 13c based on the requested function and on the available supply voltage.

Given that some parts of the DER2 which work at high voltage are not isolated, for the safety of the operator, it is necessary for the power source to be isolated from the electrical grid, for instance by a transformer.

The use of these types of connection is reserved to qualified personnel, able to assess the operational risks of high voltage and who have a full knowledge of the content of this manual.

---

Fig. 13a: DER2 48Vdc power supply (please note that no other connections, other than the power source, are necessary) for the download of the alarms without risking to modify the content of the EEPROM because of the test.

Fig. 13b: DER2 75-145Vac power supply (Please note the sensing on terminal 7 and the jumper between terminals 6 and 3 of the DER2) for test and setup

Fig. 13c: DER2 150-270Vac power supply (Please note the sensing on terminal 5 and the jumper between terminals 4 and 3 of the DER2) for test and setup
